

NATIONAL EXAMINATIONS MAY 2015

07-Mec-A1 Applied Thermodynamics and Heat Transfer

3 Hours Duration

Notes :

1. If doubt exists concerning the interpretation of any question, the candidate is urged to make assumptions and clearly explain what has been assumed along with the answer to the question.
2. The examination is open book. As a consequence, candidates are permitted to make use of any textbooks, references or notes.
3. Any non-communicating calculator is permitted. However, candidates must indicate the type of calculator(s) that they have used by writing the name and model designation of the calculator(s) on the inside of the cover of the first examination book.
4. It is expected that each candidate will have copies of both a thermodynamics text and a heat transfer text in order to make use of the information presented in the tables and graphs contained.
5. The answers to five questions, either three questions from Part A and two questions from Part B or two questions from Part A and three questions from Part B, comprise a complete examination.
6. Candidates must indicate the answers that they wish to have graded on the cover of the first examination book. Otherwise the answers will be graded in the order in which they appear in the examination book(s) up to a maximum of three answers per section .
7. The answer to any question carries the same value in the grading .

PART A - THERMODYNAMICS

1. (a) A small capsule having a volume of 5 cm^3 contains liquid water at 7.5 MPa and 60°C . The capsule is located inside an evacuated container having a volume of 0.025 m^3 . Subsequently, the capsule is broken by some appropriate mechanism so that the water is able to evaporate and fill the large container. Calculate the final density of the water/vapour mixture, assuming that water/vapour mixture can exchange heat with the surroundings through the walls of the container. Determine the heat exchange with the surroundings.
(b) An air compressor takes air in at 1 atmosphere and 20°C and discharges it into a line having inside diameter of 1 cm. The air velocity in the line close to the discharge is 7 m/s and the discharge pressure is 3.5 atmospheres. Assuming that the compression occurs adiabatically and that the inlet air velocity is small, calculate the power required to drive the compressor.
2. Steam enters the high pressure turbine of a reheat cycle power plant at 3.5 MPa and 350°C in which it is expanded to 0.5 MPa after which it is reheated to 350°C . The steam is then expanded through the low pressure turbine to 7.5 kPa. Liquid leaving the condenser at 30°C is pumped to 3.5 MPa and returned to the boiler. Each turbine is adiabatic, with an efficiency of 85%. The pump efficiency is 80%. If the total power output of the turbines is 1000 kW, determine (a) the mass flowrate of steam (b) the pump power and (c) the thermal efficiency of the power plant.
3. A stationary gas turbine power plant operates on the Brayton cycle and delivers 20,000 kW to an electric generator. The maximum temperature is 1200 K and the minimum temperature is 290 K. The maximum pressure is 380 kPa and the minimum pressure is 95 kPa. Determine (a) the power output of the turbine (b) the fraction of the output of the turbine used to drive the compressor and (c) the mass and volumetric flowrate of the air entering the compressor.
4. An ideal vapour-compressor refrigeration cycle operates with Freon-12 as the working fluid. The evaporator temperature is 15°C and the condenser pressure is 1.4 MPa. The mass flowrate of the refrigerant is 0.008 kg/s. The compressor efficiency is 80% and the liquid leaves the compressor at 48°C . Determine (a) the power required to drive the compressor (b) the capacity of the refrigerator and (c) the coefficient of performance.

PART B - HEAT TRANSFER

5. A self cleaning oven is being designed by a leading manufacturer of household appliances which features a composite window in the door of the oven comprised of two pieces of high temperature resisting plastic A and B bonded together. The thicknesses of the plastic are such that $L_A = 3 L_B$ and the thermal conductivities are $k_A = 0.18 \text{ W/m}^\circ\text{C}$ and $k_B = 0.10 \text{ W/m}^\circ\text{C}$ respectively. During the self cleaning process, the temperatures of the walls of the oven T_w and the air in the oven T_a may be considered to be 500°C and the temperature of the air in the room T_∞ may be considered to be 25°C . The coefficients of convection h_{ci} and radiation h_r inside of the oven as well as the coefficient of convection outside of the oven h_{co} may all be taken to be $25 \text{ W/m}^\circ\text{C}$. Determine the minimum thickness of the composite window $L_A + L_B$ needed to ensure that the temperature of the outside surface T_o is 50°C or less for safety reasons ?
6. A water heater comprised of a tube 10 mm diameter by 4 m long is subject to a uniform heat flux of 1000 W/m^2 at the surface. Water entering at 10°C flows through the tube at 12 kg/hr. Considering that the heat transfer coefficient varies with length along the tube as thermodynamic conditions develop, determine the rate of heat transfer and the temperature of the tube at the exit.
7. A power amplifier which may be modelled as a thin rectangular plate 40 mm high by 50 mm long for the purposes of analysis is oriented vertically in air at 25°C . The case of the power amplifier is made of anodized aluminum for which the surface emissivity is 0.82. The heat generated within the power amplifier is 7 W. Determine the temperature of the surface of the power amplifier when both natural convection and radiation heat transfer act to remove the heat.
8. Water flowing at 3.8 kg/s is heated from 38°C to 55°C in the tubes of a one shell pass / two tube pass heat exchanger. Water flowing at 1.9 kg/s enters the heat exchanger at 94°C and passes once through the shell side. The overall heat transfer coefficient is $1420 \text{ W/m}^\circ\text{C}$. The density of the water flowing in the 1.905 cm diameter tubes is 961 kg/m^3 and the average water velocity is 0.386 m/s . Because of space limitations, the heat exchanger cannot exceed 2.44 m in length. Determine the number of tubes and the number of tube passes required consistent with this limitation.

The End

Thermodynamic Properties of Freon-12 (Dichlorodifluoromethane)^a
